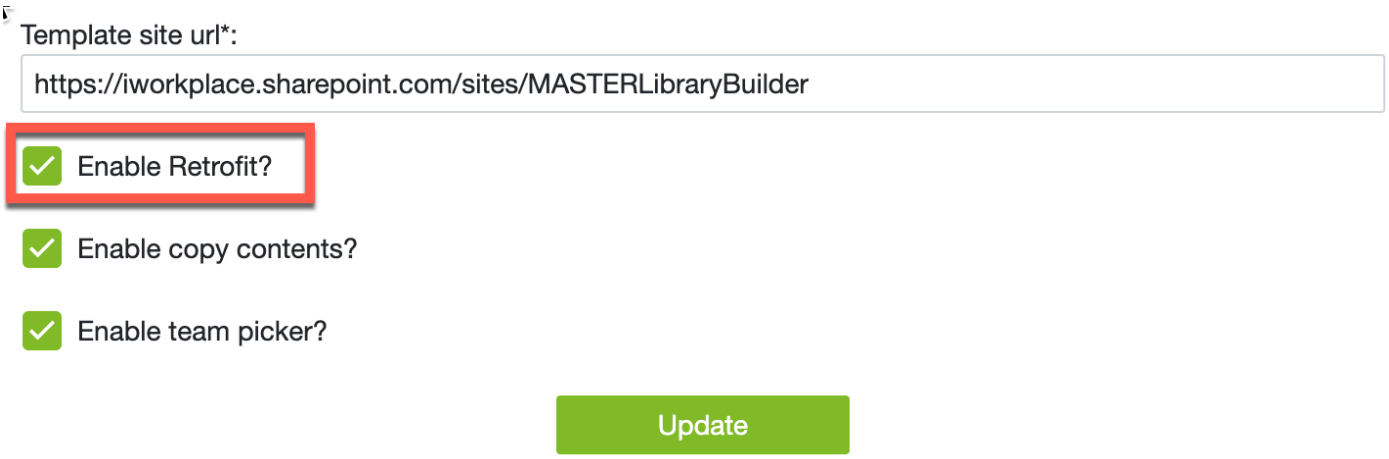
What does Retrofit do in Library Builder?

Retrofit is an option that allows the selected template to be applied to an existing library or list.

Enabling Retrofit

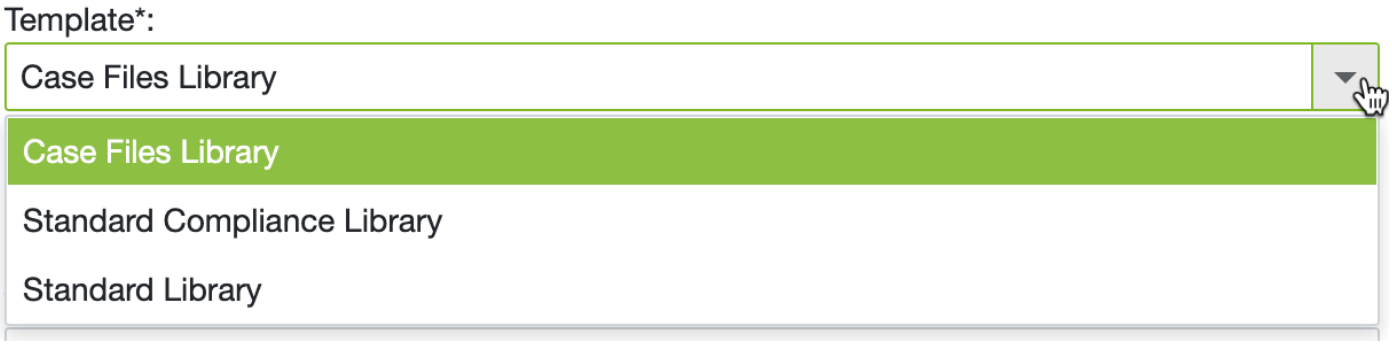
To be able to retrofit a site, retrofit must be enabled in Library Builder. To do this, Once in settings, tick *Enable retrofit?* And then select *Update*.



To Retrofit a List or Library:

1. Navigate to the *iWorkplace* page in your team, under the *Library Builder* app, click *Create List or Library*.

2. *Template* - Select the template you want to apply to the list or library from the dropdown menu.



3. *Destination* – Select the destination team you want the list or library to be built in from the drop-down menu. *Note: This step will only be applicable if Enable site picker? is toggled on within the Library Builder settings*.

4. *Title* - Enter the name of the **existing** list or library that you want to retrofit.

5. Select *Retrofit if already exists?*

6. Click *Create.*

Retrofit will Attempt to:

- Update library/lists settings (versioning, default view, etc)
- Add and update content types
- Add and update columns
- Add and update views

When using retrofit you should ensure you only use library templates for libraries and list templates for lists. Using a library template for a list and vice versa will cause issues.

How are the changes made?

Settings

All settings that library builder would set on a new list or library will be updated to match the template.

Content Types

Library Builder uses both name and ID to try and match existing content types with the ones in the template.

If the content type does not exist it will be added.

If a content type already exists in the destination, then it will be updated to match the template one. In addition - if the default content type in the destination library is called Document, and the default in the template is eDocument, then it renames the Document content type and updated to match eDocument.

If a content type exists in the destination but is missing from the template, then library builder will check if there are any items in the list or library that use that content type. If they do then the content will be left but removed from the new menu, if not then the content type will be deleted.

Columns

Library Builder uses both name and ID to try and match existing columns with the ones in the template.

If the column does not exist it will be added.

If a column already exists in the destination, then it will, where possible, be updated to match the template. There are some exceptions to this where the columns are of a different, incompatible, type. For example, a people column could not be updated to be a choice column.

If a column exists in the destination but is missing in the template it will be deleted.

Views

Views are deleted and then rebuilt in the destination to make sure they match the template.

Content

Retrofit does not update the contents of lists and libraries. For example, if the choices in a choice column change, any items with values in that column will not be updated by Library Builder. It is possible though that Autofixer will make changes later if those columns match its rules.
