SharePoint Security

These settings are managed in the *SharePoint Security* tab of the **Smart Provisioning** settings.

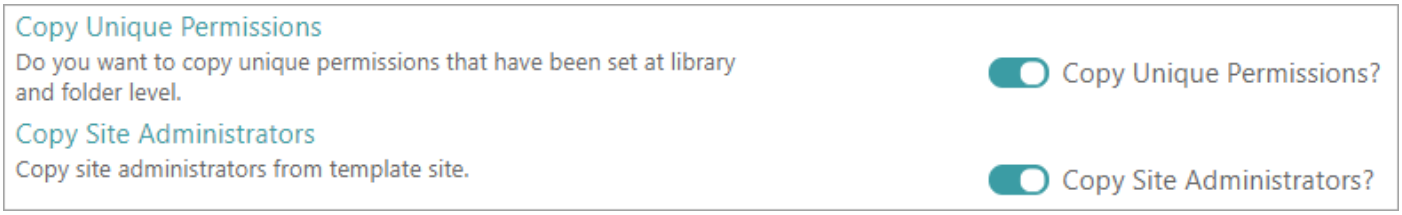
Security Type

This option is only used for modern group enabled sites. It controls the type of group and team created when the site is provisioned. Public sites are findable and accessible to all users in the organisation, while private site are 'invitation only'.

Group Names

When a *Security Column* is used to provide access to a site a security group must be created in the new site. This option lets you set if the display or internal name of the column for this security group.

Copy permissions



Copy Unique Permissions

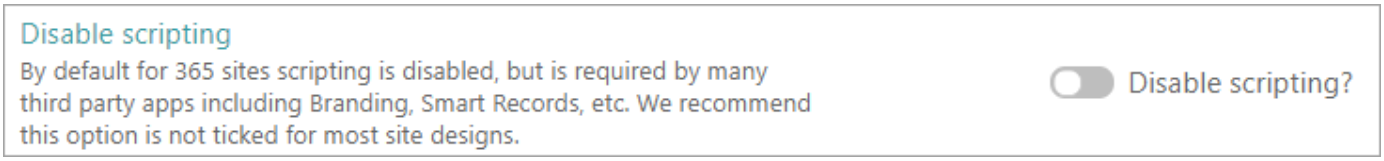
Enabling this option means that **Smart Provisioning** will attempt to copy any unique permissions that have been set on libraries at either library or folder level (when copy library contents is enabled).

This is primarily designed for user libraries, but permissions on the Site Pages library at library level will also be copied.

Copy Site Administrators

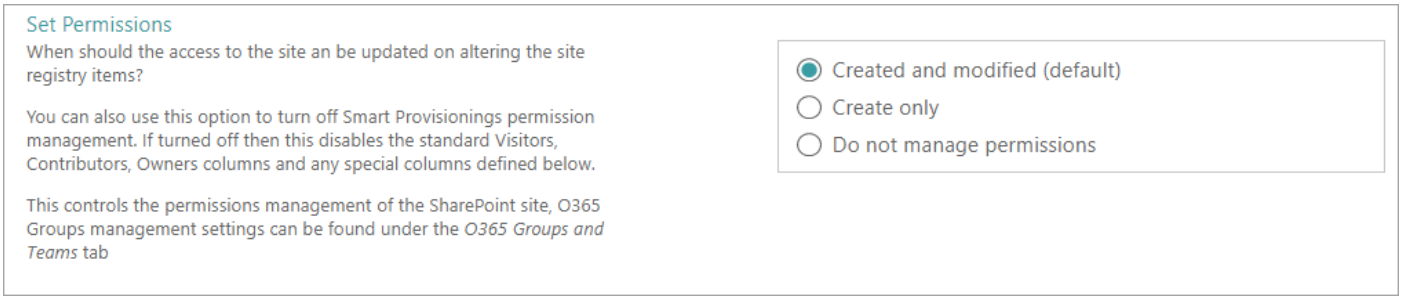
Normally site administrators are managed by the Site Admins column in **Smart Provisioning**. Enabling this option will copy all site administrators from the template site. This option can be useful if you have a set group of site admins that should be added to every site.

Disable scripting



By default, **Smart Provisioning** automatically enables scripting in new sites. Scripting is required for most 3rd party apps including iWorkplace ones and even some OOTB SharePoint functionality. This option, though not recommended, allows you to change this behaviour so scripting is disabled once the site is created.

Set Permissions



This controls when Smart Provisioning should, and should not, control who has access to the site and team.

Created and modified

This option means Smart Provisioning has complete control over access to the site. Any changes made directly by users will be overridden the next time the Smart Provisioning item is edited.

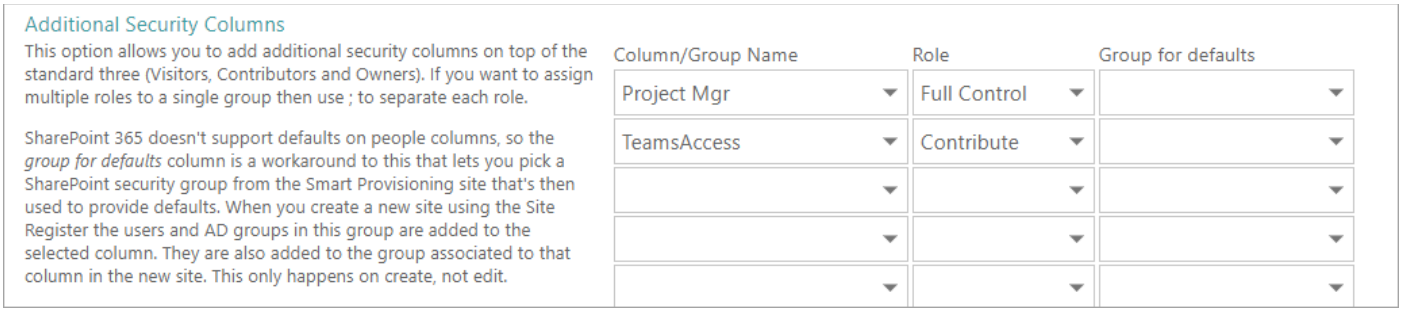
Create only

Smart Provisioning will configure all access to the site when its first created. Users can then control who has access to the site from that point onwards.

No not manage permissions

Access is not controlled by Smart Provisioning. Selecting this option will hide the *Additional Security Columns* setting.

Additional Security Columns



This option allows you define what people columns in you Provisioning Register control access to the site. You select the people column in the first column and then the role this group has in the second. Smart Provisioning will create a group in the site with the same name as the column, assign it the Role you have defined and then copy the user etc defined in the column into the group.

You can have Users, AD Groups and SharePoint Groups in your People Column. Users and AD Groups get added directly. SharePoint groups are 'unpacked' with the users and AD groups they contain being put directly into the new group.

It is important to note that the Role column options must exist within the SharePoint Site if they are to be applied. Where a Role option doesn't exist, a fallback option will be applied in its place to ensure functionality is maintained, while ensuring that elevated permissions aren't mistakenly applied.

- View Only > Read.
- Restricted Read > Read.
- Instances of other options will have Edit (which itself falls back to Contribute if it doesn't exist).

If this is to occur, the Progress column in your Site Register will show a "Has issues" link, and upon clicking that the Progress page within Smart Provisioning will inform you of this occurrence, e.g.

IMPORTANT: Permission level [Missing Permission Level] does not exist on [Site Name]. Applying [Alternative Permission Level] to [Group Name] as a fallback. Your Administrator may need to add the missing Permission Levels to this site as well as the template to resolve this issue.

Group for defaults

SharePoint does not support defaults on people columns, so this column lets you pick a SharePoint security group from the Smart Provisioning site that can be used as a default.

When you create a new site with site status of '02 Initialise' or '03 Active' this group is 'unpacked' and the users and AD groups within are added to the new group in the site. They are also added to the column in the Provisioning Register item. This only happens once, upon create, not for subsequent edits of the site asset item.

Note: default permissions are not applied to site asset items with '01 Request' status, or when such request items are progressed to site status '02 Initialise' or '03 Active'.
